[Abstract] Lipid droplets (LDs) are ubiquitous intracellular structures whose formation, growth, and maintenance are highly regulated (Wang *et al.*, 2013; Ranall *et al.*, 2011; Goodman, 2009). Lipid metabolism and droplet dynamics are of considerable interest to agriculture, biofuel production, viral pathology, nutrition, and cancer biology (Walther and Farese, 2009; Liu *et al.*, 2010). Accumulation of fatty acids and neutral lipids in nonadipose tissues is cytotoxic (Kourtidis *et al.*, 2009). BODIPY 493/503 (4,4-Difluoro-1,3,5,7,8-Pentamethyl-4-Bora-3a,4a-Diaza-s-Indacene) is the standard dye to study LDs within adipocytes. BODIPY 493/503 contains a nonpolar structure that, upon binding to neutral lipid, emits a green fluorescence signal with a narrow wavelength range, making it an ideal fluorophore for multi-labeling experiments. The hydrophobic nature of the dye molecules promotes rapid entry into the nonpolar environment of LDs (Listenberge and Brown, 2007). Gocze and Freeman showed that the lipid fluorescent variability is significantly lower when using BODIPY493/503 compared to Nile Red, suggesting that it may be more specific for the LD (Gocze and Freeman, 1994). Here, we describe a BODIPY 493/503 assay for the detection of neural fat stores in cultured cells (Figure 1) (Wang *et al.*, 2013).

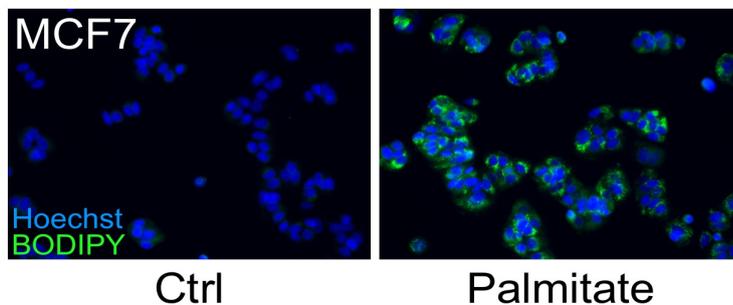

Figure 1. MCF7 cells were treated with 250 μ M palmitate or vehicle control for 24 h. A number of breast cancer cells possess a lipogenic metabolic phenotype that makes them especially sensitive to the addition of physiological concentrations of exogenous saturated fatty acids, such as palmitate. Although palmitate supplementation induces cell death in HER2/neu-positive cells, other breast cancer sub-types, including MCF-7 cells, accumulate the fatty acid which leads to significant increases in intracellular triglyceride fat stores. Cells were fixed and stained for fat stores with BODIPY 493/503 (green). Hoechst 33342 (blue) was used for nuclei staining.

Materials and Reagents

1. Cell line suitable for testing, MCF7 (ATCC, catalog number: HTB-22™) cells perform well as a staining control
2. Dulbecco's Modified Eagle's Medium (DMEM) (high glucose with L-glutamine) (Thermo Fisher

- Scientific, catalog number: SH3024301) or other media appropriate for MCF7 cell culture
3. Fetal bovine serum (FBS) (Sigma-Aldrich, catalog number: F4135)
 4. Phosphate buffered saline (PBS) (e.g. HyClone, catalog number: SH30258-02) or Dulbecco's phosphate buffered saline (with Ca^{2+} and Mg^{2+}) (DPBS) (e.g. Sigma-Aldrich, catalog number: D1283)
 5. Sodium palmitate, (used as positive control) (Sigma-Aldrich, catalog number: P9767)
 6. Dimethyl sulfoxide (Sigma-Aldrich, catalog number: D8418)
 7. BODIPY 493/503 (4,4-Difluoro-1,3,5,7,8-Pentamethyl-4-Bora-3a,4a-Diaza-s-Indacene) (Life Technologies, catalog number: D-3922)
 8. 37% formaldehyde (Thermo Fisher Scientific, catalog number: F79)
 9. Hoechst 33342 (Life Technologies, catalog number: H21492)
 10. 500x BODIPY 493/503 stock solution (see Recipes)
 11. 10,000x Hoechst 33342 stock solution (see Recipes)

Equipment

1. 96-well tissue culture plate suitable for imaging, (e.g. Corning, Costar®, catalog number: 3603)
2. Cell culture incubator at 37 °C with 5% CO_2
3. Fluorescence microscope or automated imaging system (e.g. IN Cell Analyzer, GE Healthcare)

Procedure

1. Plate 10,000-20,000 cells per well in 100 μl DMEM high glucose with L-glutamine, 10% FBS, in the 96-well plate. Doing a serial dilution can be helpful to determine the effect of cell number on BODIPY intensity.
2. Incubate the cells at 37 °C overnight.
3. Dilute the sodium palmitate stock solution in pre warmed DMEM high glucose with L-glutamine, 10% FBS. A range of 50-500 μM is useful to demonstrate BODIPY-based lipid content relative quantification. Prepare appropriate vehicle controls.
4. Carefully aspirate medium from the 96-well plate and replace with treatment medium (use 100 μl per well).
5. Incubate the cells at 37 °C overnight.
6. Prepare a 5% formaldehyde solution in PBS. Add 100 μl per well directly into the tissue culture medium to achieve a final formaldehyde concentration of 2.5%.
7. Incubate for 15 min at room temperature.
8. Prepare the staining solution; dilute the BODIPY and Hoechst stock solutions in PBS to a working concentration of 10 $\mu\text{g/ml}$ BODIPY and 1 $\mu\text{g/ml}$ Hoechst. Calculate 100 μl per well. Both dyes can be added in parallel, there is no need for sequential staining.
9. Carefully remove the formaldehyde from the cells and wash twice with 100 μl of PBS per well.
10. Add 100 μl staining solution per well.
11. Incubate for 30 min at room temperature, in the dark.
12. Wash twice with 100 μl of PBS per well.
13. Remove PBS, add 130 μl of PBS per well (only required for IN Cell Analyzer).
14. BODIPY and nuclei Hoechst fluorescence are imaged and quantified using fluorescence

microscopy with appropriate filter sets. Our laboratory makes extensive use of the INCell Analyzer 2200 and INCell Investigator software for these measurements. Fluorescence intensity per cell is proportional to the neutral lipid content in the cell.

Notes

1. Solubilize sodium palmitate in DMSO at 75 mM immediately before usage, do not store.
2. If many cells are lost from the plate during washing with regular PBS, use DPBS for washing and preparing working solutions of BODIPY and Hoechst.
3. Care should be taken to stain at approximately equal cell densities when comparing different cells or culture conditions.

Recipes

1. 500x BODIPY 493/503 stock solution
Solubilize BODIPY 493/503 in DMSO at 5 mg/ml
Aliquot and stored at -20 °C in the dark
2. 10,000x Hoechst 33342 stock solution
Solubilize Hoechst 33342 in DMSO at 10 mg/ml
Aliquot and stored at -20 °C in the dark
